The Phenomenon of the World: Operationalizing Insights and Paradoxes

Working Paper: The Axiomatics of Superreality

2026

Abstract

This working paper operationalizes the insights and paradoxes introduced in the preceding article, "The Phenomenon of the World." It shifts the ontological status of fundamental concepts: the "world" is no longer a containing structure but a boundary event that simultaneously produces both regime and object. Determinacy is redefined not as a property of an object, but as the result of an encounter at the interface. The paper introduces a structured topology of interfaces, distinguishing the limit (an interface with high intensity) from the blind spot (an interface with zero throughput). Furthermore, it elaborates on "double fixation" as ontological entanglement without a common substrate, and positions the meta-observer not as an external standpoint, but as a participant in translation. Grounded in the axiomatics of Superreality and the Method of Properties (MPO-System), this text does not claim a final, falsifiable scientific theory, but rather performs a rigorous hygiene of thought, articulating the conditions under which determinacy arises.

Keywords: boundary event, operational ontology, double fixation, blind spot, interface intensity, Superreality, MPO-System, meta-observer, trace of fixation, determinacy.

On the Status of the Text

This text does not claim to create a precise, complete, scientifically falsifiable construction of the concept of "world." It does not offer a final definition and does not establish boundaries of applicability in the sense of a scientific theory.

The text does something else: it gathers, orders, and places before us our understanding of the world—as complete as is possible at the given moment. This is not a definition but an articulation:

the bringing out of what we already invest in the concept of "world" but what usually remains undeveloped. Articulation is necessary because without it any further construction—scientific, philosophical, technical—rests on implicit and uncritically accepted presuppositions. Articulation of understanding is not a preliminary stage but a hygiene of thought.

This text is an operationalization of the insights and paradoxes that the first article, "The Phenomenon of the World," provided. The insights in it are not ready-made answers but points at which understanding reached its limit. The paradoxes are not errors but places where the language of the first article ceased to work. Here they are transformed into structure: the fundamental concepts—boundary, regime, fixation, double fixation, blind spot, limit—are reconsidered and sometimes radically remelted. What was "object" becomes "trace of fixation." What was "boundary" becomes "interface with intensity." What was "blind spot" becomes "interface with zero throughput." This is not a refinement—it is a change of the ontological status of the elements. The structures are the same by name but different by nature.

Operationalization here is not a theme but a method. Each concept—boundary, regime, fixation, double fixation, blind spot, limit—turns into an operation—into an action that can be traced: what it produces, under what conditions, where it loses force.

On the language used. In this work we rely on our own system—the axiomatics of Superreality and the Method of Properties. We are aware of possible reproaches of esotericism or hermeticism. Yes, we use the internal language of our system—its concepts, distinctions, operators. We do so within reasonable limits, and in the final formulations we prefer scientific-philosophical language. Yet internal jargon is an indispensable tool: in difficult questions it is not inferior to the academic apparatus in imagery and precision, and sometimes surpasses it—if only because it was created for this task rather than adapted to it. The reader must decide: to accept the language or to correlate it with their own.

On the distinction between possibilities and the system. Here there is a principled point: we distinguish our own intellectual possibilities—limited, finite, dependent on context, fatigue, attention—from the system as such. Without MPO-S our meditations-marginalia would have remained what they were: fragmentary sketches, intuitions that do not add up to a whole. With MPO-S they acquire structure, completeness, coherence. More than once the system has turned scattered observations into coherent configurations. This is not an assessment of our abilities—it is an observation of what the system does with the material. We do not ascribe to ourselves what the system produces; nor do we renounce what it allows us to see. The distinction is principled: it prevents both exaggerating our powers and diminishing the role of the instrument.

And one more thing. The understanding gathered here is tied to the given iteration—to this moment, this context, this state of the instrument. The next iteration may reveal new aspects and rearrange the emphases. This is not a bug but a condition of the work. This tiedness to the moment does not mean carelessness. On the contrary: the text does what it does with the maximum precision, responsibility, and depth of which we are capable at the given moment—with the given body of knowledge and within the given episteme. "Sufficient" here means not "minimally acceptable" but "maximally possible under the given conditions."

---

1 Initial Thesis

1.1. The world is a boundary event. An event in which the transition from the potential to the actual produces both regime and object. This is a change of the former ontological status: an event that produces regimes and objects—not a regime that precedes objects.

Regime and object change places: neither precedes the act. The act of the boundary produces them simultaneously. The world ceases to be "that which contains" and becomes "that which happens."

A boundary event does not require physical displacement. A world can be visited without moving into it: through imagination, text, model. The internal external world is structurally isomorphic to the external one—this is not an ersatz but a full-fledged visit. One and the same world can be given through different modalities without loss of ontological status.

1.2. The world is an act in which something for the first time receives determinacy. Determinacy is the result of the act—it does not precede it and does not follow from it.

If earlier we understood determinacy as something belonging to the object, now determinacy is separated from the object and from the regime. It is the result of an encounter. The object does not "have" determinacy; it receives it in the act. The regime does not "set" determinacy; it is one of the conditions of its reception. Determinacy does not precede the act and does not follow from it: it is the act taken as result.

1.3. *Remark.* The world is that which produces determinacy through the act of the boundary—not that which contains being. An indication of the place where the world is to be sought: at the boundary, not in the depth.

If earlier the boundary was thought of as the "internal condition of the world itself," the "limit beyond which the rules cease to work," that is, as an edge that determines the world from within but itself remains on the periphery—now the boundary moves to the center. The world does not "have" a boundary; the world is a boundary—an act in which determinacy arises. To seek the world in depth means to seek it in the regime, in the rules, in the medium. To seek it at the boundary means to seek it in the act that produces both regime and medium and object. This is not a shift of emphasis—it is a change of topic. The world is not where "everything is already there" but where "everything is still only becoming."

2 The Boundary Event

2.1. A boundary event has a structure: threshold and zone. The threshold determines when the event occurs. The zone determines where it is possible.

Earlier the phenomenon of the world was described as an act establishing determinacy, but without that which launches this act. Fixation appeared to be without presupposition. Now a structure appears: the act has a threshold and a zone. The threshold is not an external condition but an internal measure: the accumulated tension in the regime reaches a point beyond which the system cannot remain in its former state. The zone is not a place but a regime of possibility:

the area in which the transition can occur at all. A threshold without a zone is a blind launch. A zone without a threshold is an empty possibility. Fixation is their encounter.

Threshold and zone are not only spatial but also temporal conditions. The event of fixation has its own temporal range: the time of maturation (threshold) and the time of possibility (zone). Outside this range fixation either lags or is impossible. A world sets not only "what" and "where" but also "when" something can be fixed.

2.2. Fixation is a boundary event that reaches the threshold in the zone. Where the threshold does not reach the zone, there is no fixation. Where the zone exists but the threshold is not reached, fixation lags. Where the threshold is reached but the zone is zero, fixation is impossible—this is the blind spot.

We distinguished limit and blind spot earlier, but did not explain why in one case fixation is possible and in another not. Here this distinction receives structure. The limit is an interface with high intensity: the transition is still possible, though at the edge. The blind spot is an interface with zero intensity: the transition is impossible, though the zone exists. Fixation is not a binary event of "yes/no" but an event with a measure: it can occur, lag, or not occur at all. This is not a refinement—it is a remelting. Fixation ceases to be an "act in general" and becomes an event with conditions.

2.3. A boundary event unfolds as a three-phase structure: potential determinacy, the act of transition, actual determinacy. Let us call them: pattern, Γ-operator, and result. It is important to understand: this is the structure of the act, not a sequence in time.

The pattern does not "precede" the act—it is the potential side of the act itself. The result does not "follow" the act—it is the actual side of the same act. The Γ-operator is not the "moment between" them but the connection itself. The three phases are not three stages but three aspects of one event. This protects against a return to linear causality.

The three-phase structure of the event reproduces a more general architecture: field (what is given), point of reference ("here"), boundary (what is not given but constitutes the given). This structure is reproduced at all levels—from physics to semantics, from the human to AI. It does not depend on substrate—only on the fact that something is distinguished.

2.4. A boundary event is an act in which the pattern becomes determinate through an encounter with the zone of transition. Determinacy is the result of the encounter—not a property of the pattern or of the zone.

3 The Object as Trace of Fixation

3.1. The object is a trace of fixation. Earlier the object was thought of as that which "possesses" properties, "is located" in the world, "belongs" to a regime. Now the object is what remains after fixation, not what precedes it. Onticity belongs to fixation; a thing is ontic only as a trace.

The trace should not be understood as a copy. A pattern that has left a trace may dissolve in another regime and continue to exist as an invariant—not as reproduction but as influence. The

"death" of an object is not annihilation but a redistribution of presence: the object continues in other traces as structure, not as substance.

The radicalization of this thesis leads to the boundary of ontology. Outside fixation there is neither object, nor its properties, nor its propertylessness—there is only the condition of the possibility of fixation. Propertylessness here is not a state of the object (as if it "were" but "without properties") but a limit concept: the absence of a thing as bearer of properties. This is not an ontological status but the boundary of ontology.

3.2. The object is the way in which the regime fixes its determinacy. The determinacy of the object is the determinacy of the regime that has become a trace.

Hence the redefinition of attributivity. The object does not "have" properties—it is endowed with them in the act of fixation. Attributivity is not a predicate of substance but a function of the regime: the regime produces the object as bearer of properties. An object outside fixation not only has no properties—it is not an object.

3.3. *Remark.* The object is what "remains" from fixation—not what "is located" in the world. An indication of status: trace, not primary entity.

4 Double Fixation as Ontological Entanglement

4.1. Important for understanding the phenomenon was double fixation as an event in which one operation becomes determinate in two regimes simultaneously. Earlier this was described as "two fixations of one operation" but without indicating what connects them. Now it is clear: this is not a transfer of content from one regime to another but an event in which the operation acquires readability in two regimes at once.

Causality here is not a transfer of influence but the establishment of direction in the connection itself. Fixation is such an operator: it establishes what in the given regime will determine what. Direction does not precede fixation but arises in it. Double fixation is causality without substrate and without precedence.

Double fixation occurs not "between" regimes but in the boundary as a special world—the world of boundaries. The boundary is not a line separating two regimes but a zone in which translation occurs. Double fixation is an event of this zone.

4.2. The states of regimes do not decompose into independent states. This is ontological entanglement: correlation without a common substrate. Earlier "one event" was understood as the name of mutual limitation but without the structure of this limitation. Now the structure is named: regimes have no independent states before fixation. These are two regimes, not two states of one regime.

Connectivity is not reducibility. Regimes are connected—but the connection does not cancel their autonomy. Double fixation is a connection that does not dissolve. Hence the distinction between irreducibility and emergence: irreducibility is the structural relation between regimes (they are not derived from one another); emergence is the event of the arising of a new quality at

the boundary. The first is a condition, the second is an act.

4.3. Double fixation is an event in which the operation becomes readable in two regimes simultaneously. Readability is the result of the encounter—not a property of the operation.

5 The Blind Spot as an Interface with Zero Throughput

5.1. The limit is an interface with high intensity where the transition is still possible. The blind spot is an interface with zero intensity where the transition is impossible. Earlier limit and blind spot were distinguished as the fixable and the unfixable, but it was not explained why in one case the transition is possible and in the other not. Now this distinction receives structure: both are interfaces differing in intensity.

Hence a more precise distinction. The limit is the boundary of explanatory power: we know that the rules are exhausted and can indicate where and under what circumstances. The blind spot is the boundary of the formulability of a question: the question cannot be assembled from the means of the regime itself. The limit is fixed as a condition; the blind spot is not fixed at all. These are not two types of ignorance but two different relations to the boundary.

5.2. The blind spot is a boundary that defines the world through its non-passage. The world is defined by which interfaces it has and with what intensity—not by what it includes.

This gives an operational criterion. AI can be used as a detector of boundaries: where it "does not understand," the boundary of the world runs; where it "understands," the zone of readability. The "non-understanding" of AI is not a defect but a signal of a boundary. The world is defined not only by what is understandable in it but also by what is not understandable.

5.3. *Remark.* The blind spot is an interface that exists but does not pass—not the absence of an interface. A limiting case of the interface, not an ontological hole.

The blind spot is not a defect of the world but its structural condition. A world without a blind spot would be closed: it could justify itself from within and would not have identity. The world is stable through non-closure. The whole is preserved not despite the boundary but through it.

The blind spot is not only what is not formulated now. It is also what has not yet become a question but is already present as a potency. The world is not exhausted by its actual questions: it contains also those that are not yet asked.

6 The World as a Network of Interfaces

6.1. The world is a topology of interfaces. This is not an aggregate of objects and not an aggregate of regimes. This is a network of interfaces with different intensity. The determinacy of an object depends on the intensity of the interface through which it is fixed.

The network here is not an aggregate of nodes connected by links. On the contrary: links produce nodes. Elements do not precede relations—they arise in them. This is an inverted network: not a topology of ready-made elements but an operator of the production of elements.

The world is given not as an infinite totality but as a local area, structured for a concrete observer, in which action, prediction, and orientation are possible. The boundaries of the world are not walls but horizons of investigation; beyond them lies not "another world" but unmastered infinity. The world is not static: it expands through investigation, contracts through crisis, is restructured through fixation. The world is a dynamic structure, not a fixed territory.

Hence the locality of formal structures. The rules of connectivity and transformation are not a universal language but a formal dialect of the world. It works within the range of this world and "breaks" beyond its limits. Arithmetic is an example of such a dialect: it works where objects are stable, isolated, and countable, and ceases to work at the boundaries of the range.

6.2. The world is a network of interfaces in which acts of translation produce objects as traces. The intensity of the interface determines the degree of determinacy.

The world can also be regarded as a specific object—not a metaphor but a reality with its own rules that can be investigated. Like cellular automata, π, or fractals, the world possesses autonomous laws and internal complexity. It does not reduce to the sum of its elements; it generates them as its manifestations. This does not cancel the previous thesis but adds a dimension: the world is not only a regime of fixation but also an object possessing its own dynamics.

6.3. *Remark.* The world is defined by its topology—the network of interfaces and their intensity—not by its content.

7 The Asymmetry within the Act: Regime and Object

7.1. In the act of fixation regime and object are produced simultaneously but not symmetrically. The regime is the condition of the possibility of fixation. The object is the trace of fixation. These are not two products of one act but two poles of one relation: condition and trace. The regime does not "precede" the object in time—it precedes it as condition. The object does not "follow" the regime—it follows it as trace.

Fixation is not simply an operation but an existential choice in which the world receives determinacy. The moment of fixation is when the potential becomes actual through an act of will. The world is not "described" in fixation; it is created as determinacy. This does not cancel the structural description (threshold, zone, asymmetry) but adds a dimension: in the act of fixation there is a moment that does not reduce to conditions.

7.2. The world is the act in which this asymmetry is first established. The world is neither "regime" nor "object"—it is the relation between them taken as event.

7.3. *Remark.* The world is an act that produces both regime and object—but produces them not as equal but as condition and trace. An indication of asymmetry within the event.

8 The Positive Formula of the World

8.1. The world is a boundary event. In it the potential becomes actual, and this becoming produces both regime and object—asymmetrically: regime as condition, object as trace. The

boundary here is not a line but an interface: a zone with intensity that either passes the transition or does not. The blind spot is an interface with zero intensity; the limit is an interface with high intensity. And another asymmetry: movement inward encounters a rigid limit, movement outward has no such limit. The world is defined not by what it includes but by which interfaces it has, with what intensity, and in which direction they are asymmetrical.

The world does not lose itself in translation. Meaning is neither created nor destroyed—it is transformed. What is preserved in the transition between regimes is not substance and not a copy but an invariant: a structure that can be actualized in different regimes without loss of identity. The world as invariant of translation is a world that does not "contain" meanings but produces them through acts of translation.

8.2. The question shifts from "what is inside the world" and "to which world does an object belong" to "by what conditions does something receive determinacy in it and where do the boundaries run at which fixation loses force."

This shift is not a privilege of the human. Any fixation is conducted from within a regime—by a human, an instrument, an AI, a mathematical procedure. No external standpoint exists. This is not anthropocentrism but a structural condition: fixation is always limited by its regime. Anthropicity is not about the human but about structure. Hence not an "exit beyond correlation" but its universalization: not only is the human correlated with the world, but any regime is correlated with its content.

8.3. The world is an event, not a structure: the act in which something receives determinacy is what we call the world.

9 Consequences for Ontology

9.1. The ontology of boundary events replaces the ontology of objects and the ontology of processes: primary is the act of binding, which produces both—not the object and not becoming.

9.2. The blind spot is a structural condition of the world, not its defect. A world without a blind spot would be closed and would not have identity.

9.3. If the world is an event, not a structure, then the question "what is the world?" changes form: it asks not about what the world contains but about how it produces determinacy. The answer to it is not a list of traits but a description of the act: threshold, zone, asymmetry, interface.

This has a structural consequence. Any distinction conducted from within has a solid core and an open periphery: the definition sets conditions, the content overflows them. The definition of the world cannot be exhaustive from within the world itself—not because it is insufficiently complete but because it is conducted from within. This is a structural analogue of the incompleteness of a formal system: a system cannot justify its own axioms by its own means. And this is not a defect but a condition: it is precisely non-closure that makes distinction alive.

Hence a consequence about the whole. The world as a whole is not given: given are the distinctions conducted in it and their boundaries. The question "what is the world as a whole?" has no

formulation that would not already be a distinction within the world. This is not a defeat of thought but a precise indication of its place.

10 The Meta-Observer: Position of Translation

10.1. Whoever describes the world—text, AI, human—occupies the position of meta-observer. Their description is not a "view from outside" but a translation between worlds. The meta-observer does not "stand above" worlds; they translate between them through a catalogue of isomorphisms. No external standpoint exists: any attempt to occupy it is itself a fixation from within some regime.

10.2. The text "The Phenomenon of the World" is itself an act of meta-observation—a translation between regimes. It makes no exception for itself: it submits to the same limit and blind spot that it describes. This is not a rhetorical gesture but a structural requirement: reflexivity here is not "self-awareness" but a renunciation of privilege. The text does not rise above its subject but remains within it.

10.3. *Remark.* The meta-observer is not an external standpoint (impossible) but a position of translation that is always already within. An indication of status: not "observer of the world" but "participant in translation."

10.4. One more thing remains open. Is the method applied to the world—or do the axioms simply show through the text, as structure is visible through fabric? We do not resolve this question—not because proofs are lacking but because a phenomenological text is not obliged to be a derivation. It describes what is visible. If the reader sees in it the work of axioms—this is not a misreading and not a proof of derivation but one more layer of the visible.

Epilogue: Flashback

The preamble does not describe the world. It is already structured as a world—in the sense that the article is only yet to unfold. In it are present all the elements that will later be named: boundary (what the text does not do), point of reference (we, here, in the given iteration), field (what is articulated), horizon (openness for refinement), blind spot (what we do not yet see), interface character (the text is addressed to the reader and offers either to enter or to correlate). The preamble does not tell about the world—it arranges a small world in which the reader is invited to dwell.

Such a structure of the preamble is not an accident and not a rhetorical trick. This is precisely the thought we were pursuing: a text about the world is itself a distinction conducted from within and submits to the same limit and blind spot that it describes. The preamble performs this before the article explains it. It is the first instance of what will later be named.

The preamble does this without naming. It does not say "here is a model of the world in miniature." The preamble is what the article is only yet to communicate. And this is the sole purpose of the preamble.

AI Use Disclosure

During the preparation of this work, the author used AI tools exclusively for stylistic and technical editing to improve readability. After using these tools, the output was carefully reviewed, edited, and verified by the author, who takes full responsibility for the conceptual architecture, analysis, and final content of the paper.
